Submitted for the degree of Naval Engineer in the Department of Naval Architecture and Marine Engineering on May 18, 1951.

Three Geometrically Similar engines are installed in Sloan Laboratory for the purpose of investigating the effect of size on engine characteristics and performance.

A theory has been formulated, which states that in similar engines operating at the same piston speed, if the ratio of oil viscosity to bore (characteristic dimension) is the same for all engines, then IMEP, FMEP, BMEP, and indicated thermal efficiency will be the same.

Previous investigative work on the OS engines has resulted in poor correlation of FMEP firing and but slightly better correlation in FMEP in the motorizing condition.

The purpose of this thesis was to motor the engines in several stages of assembly, to systematically determine the mechanical friction contribution of each engine part. These results were then compared for the three engines in an effort to determine the source of disagreement.

This work finds that within the limits of experimental accuracy the motorizing FMEP and MMEP do conform to theory. The data collected on the smallest of the three engines is at variance with that previously obtained, and essentially resolves the past disagreement with the theory.

The presence of a contact type rubber oil seal may contribute as much as 20% of the total friction mean effective pressure motoring in the completely assembled condition.

It is recommended that more firing data be collected to check previous information on firing FMEP and that the contact type oil seals be replaced with non-contact seals.

ANSWER TO THIS

which corresponds to the first part of the question. The second part of the question asks for the answer to the question "What is the value of $\frac{1}{2}x^2 + 3x - 1$ when $x = 2$?". To answer this question, we substitute $x = 2$ into the expression $\frac{1}{2}x^2 + 3x - 1$. This gives us $\frac{1}{2}(2)^2 + 3(2) - 1 = 4 + 6 - 1 = 9$. Therefore, the value of $\frac{1}{2}x^2 + 3x - 1$ when $x = 2$ is 9.

ANSWER

Let's start by simplifying the expression $\frac{1}{2}x^2 + 3x - 1$. We can factor out a $\frac{1}{2}$ from the first two terms: $\frac{1}{2}x^2 + 3x - 1 = \frac{1}{2}(x^2 + 6x) - 1$. Next, we can complete the square for the expression $x^2 + 6x$. To do this, we add and subtract $(\frac{6}{2})^2 = 9$ inside the parentheses: $\frac{1}{2}(x^2 + 6x + 9 - 9) - 1 = \frac{1}{2}(x + 3)^2 - 9 - 1 = \frac{1}{2}(x + 3)^2 - 10$. Finally, we substitute $x = 2$ into the expression: $\frac{1}{2}(2 + 3)^2 - 10 = \frac{1}{2}(5)^2 - 10 = \frac{1}{2}(25) - 10 = 12.5 - 10 = 2.5$.

INTRODUCTION

Three geometrically similar internal combustion engines, designed and constructed under the supervision of the Automotive Division of the Mechanical Engineering Dep't of the Massachusetts Institute of Technology were installed in Sloan Laboratory during 1947. These engines were built primarily for laboratory investigation of theoretical similitude relations concerning piston engines. The establishment of a general geometrically similar engine theory offers attractive possibilities in developing a basis for rational engine design, as contrasted to wholly empirical engine design. It could also permit of wider application of use of model or small scale engines in determining characteristics of large machines.

GSE Theory states that in G.S. engines operating at the same piston speed, IMEP, FMEP and MMF must be the same for all engines, if the ratio of absolute oil viscosity to a characteristic dimension is the same for all engines (5).

The only previous work which has been accomplished on these engines was that of Gaboury et al (1), Breed and Jowdry (2), Lobdell and Clark (3), and Mikel and McSwiney (4). The thesis by Gaboury et al indicated that IMEP in the three engines operating at the same piston speed conformed quite closely to predicted results. However the measured MMF did not agree with theory due to variations in FMEP. Gaboury's work included both firing and motoring runs and showed somewhat better agreement in the motoring condition than when firing.

The purpose of this investigation is to determine the mechanical friction contribution of the major components of each engine to the FMEP in motoring condition. It was hoped that such data might provide an understanding of the reason for the variation of FMEP between the three engines. Also it would serve to check previous work.

the highest positive evidence toward certain effectiveness need not be regarded as the primary warrant for a particular new value because it could easily be justified by a number of other reasons. The first problem is to find out whether the evidence of the new value is really good enough to warrant its acceptance. This problem is particularly important in the case of a new value which is not based on any previous value, but is derived from some other source. In such cases, the new value must be shown to be of equal or greater importance than the old one, and this can only be done by comparing the two values. If the new value is found to be of equal or greater importance than the old one, then it can be accepted as a valid new value.

change would have had to go through various local or rural bodies which were established to plan and regulate the use of open land for agriculture, pastures, etc. To continue the use would not be without considerable risk of ultimately losing the services which are indispensable for maintaining the soil, for example by leaving the land fallow, or by reducing the amount of manure used. The question has to be asked whether the local bodies have been given sufficient power to manage their lands in accordance with the principles of sustainable development. This is particularly important in view of the fact that the local bodies are responsible for the protection of the environment and for the promotion of the welfare of the rural population.

processes and their effect upon the development stages and the environmental conditions in which they live and their developmental conditions upon them (Fig. 2 and 3). In some cases, the control stage is conditionally constant

EQUIPMENT

The three engines under discussion are single cylinder, four stroke, spark ignition machines of 2½, 4, and 6 inch bores. All engine dimensions and accessory equipment are proportioned in the same ratio as the bores (5). Dynamometers on the 2½ and six inch engines are at the alternating current drive type with Dymatic magnetic speed control clutches. The 4 inch engine is equipped with a conventional direct current dynamometer. All machines are equipped with a sensitive hydraulic torque measuring device (7). Each engine is installed in an individual test cell mounted on a spring-supported bed plate complete with inlet surge tank, vaporizing tank and exhaust surge tank. Cooling water is circulated by a separate pump, and temperature controlled through a steam jacketed heat exchanger. A circulating oil pump is provided for a high velocity oil circuit through the crankcase and heat exchanger. This provides close and homogenous temperature control of the lubricating oil. An additional oil pressure pump is installed for bearing and cylinder lubrication. Oil and water circuits are fitted with direct-reading thermometers. A thermocouple is installed at the main bearing surface in each engine. A diagrammatic sketch of the equipment and arrangement may be found in appendix "A".

PROCEDURE

Each engine was motored in three different conditions of assembly, as described below and shown by sketch in Appendix "B".

Condition "A": Engine completely assembled. Friction elements are two main bearings, crank journal, piston and rings, timing gear drive yoke bushing, main oil seal, timing gears and bushings, camshaft bearings, cam followers and valves. No inlet and exhaust pipes were fitted, nor was the ignition equipment.

Condition "B": Crankshaft, cylinder, piston and connecting rod installed. No cylinder head, camshaft gear or valve pushrods. Friction elements are as in Condition "A" without idler gear and valve train.

Condition "C": Crankshaft and idler gear installed. No cylinder, piston, connecting rod or camshaft gear. Friction elements are two main bearings, timing gear drive yoke bushing, timing pinion, idler gear and the main oil seal. On these runs an aluminum sleeve was placed over the crank journal to prevent loss of oil pressure.

In each condition the engines were operated over a speed range from zero to 1680 feet per minute piston speed. Oil temperatures were held constant at 150° F., circulating water inlet at 180° F., circulating water flow rate was held constant at one value of flow per unit area. In collection of all data sufficient time was allowed for equilibrium conditions to prevail. A series of readings were observed at each run to show systematically that conditions were substantially constant.

In previous work on the engines, no attempt had been made to measure or regulate the jacket water flow rate. For this investigation A.B.C.T. square edged standard orifices were inserted into the water circulation system and calibrated. The first work conducted on the 2½" engine then consisted of a series of runs to determine what effect, if any, variation

differentiate among those groups that have the same disease.

The first question is whether or not a molecular approach can identify subgroups of patients with different prognoses. In other words, can we identify groups of patients who have different survival times? This is the question that has been addressed by several groups. The results of these studies are summarized in Table 1. The first study, by Gruenwald et al.,¹⁰ examined 100 patients with glioblastoma multiforme. The patients were divided into two groups based on their tumor grade. The first group consisted of patients with grade III glioblastoma, and the second group consisted of patients with grade IV glioblastoma. The patients were followed for a median of 12 months. The overall survival rate was 50% at 12 months for both groups. The second study, by Hildebrand et al.,¹¹ examined 100 patients with glioblastoma multiforme. The patients were divided into two groups based on their tumor grade. The first group consisted of patients with grade III glioblastoma, and the second group consisted of patients with grade IV glioblastoma. The patients were followed for a median of 12 months. The overall survival rate was 50% at 12 months for both groups.

The third study, by Gruenwald et al.,¹⁰ examined 100 patients with glioblastoma multiforme. The patients were divided into two groups based on their tumor grade. The first group consisted of patients with grade III glioblastoma, and the second group consisted of patients with grade IV glioblastoma. The patients were followed for a median of 12 months. The overall survival rate was 50% at 12 months for both groups. The fourth study, by Hildebrand et al.,¹¹ examined 100 patients with glioblastoma multiforme. The patients were divided into two groups based on their tumor grade. The first group consisted of patients with grade III glioblastoma, and the second group consisted of patients with grade IV glioblastoma. The patients were followed for a median of 12 months. The overall survival rate was 50% at 12 months for both groups.

in coolant flow rate would have on engine friction results. On all subsequent runs a water flow of .024¹/sec./in.² was arbitrarily used.

In concluding the first series of high speed runs on the 2 $\frac{1}{2}$ " engine in "B" condition, a sudden change in friction and bearing temperature measurements indicated the possibility of a bearing derangement. The engine was dismantled and flaking off of the babbitt in the outer main bearing was discovered. Previous difficulty had been experienced with these bearings in that the very thin babbitt layer (.005") had not been fully bonded to the backing material. Several attempts at manufacture of new bearings also resulted in poor babbitt bond, so both main bearings on this engine were changed using solid phosphor bronze as the bearing material. Investigation of bearing clearances at this time showed that the connecting rod bearing clearance was not as specified by similitude requirements. To rectify this a bronze conrod bearing was installed with clearance increased from .001" to .0025". Therefore when the 2 $\frac{1}{2}$ " engine was returned to service all three principle bearings had been changed to bronze with increased clearance in the connecting rod bearing.

Early in the investigation, in using the magnetically-coupled type of dynamometer it was noticed that the hydraulic torque-scale zero reading varied appreciably depending upon whether the zero was set with the dynamometer motor running or with the entire machine shut down. By disconnecting the dynamometer output shaft from the engine, it was determined that some form of drag existed in the magnetic coupling even with no excitation on. As a result all scale zeroes were set with the dynamometer completely off. A small possible error was also detected as related to the cooling water flow through the dynamometer. Insofar as cooling water is required for normal operation, this valve was left open when setting the scale zero.

At every opportunity measurements were taken of principal engine parts and recorded in Appendix E. The 2 $\frac{1}{2}$ " engine rings were found to have considerably more relative spring tension than the other two engines and were subsequently modified to conform more closely with similitude requirements.

After completing all other experimental runs, the main oil seal was removed from the 2 $\frac{1}{2}$ " engine and the engine run in the "B" condition to determine the magnitude of the friction contribution of this oil seal.

that makes it easier to just move between windows more easily.
Another nice thing was that the file and directory names had
the same encoding as code so you could quickly switch between
different files without having to constantly re-type the path.
And since IIS didn't have checkboxes with the `checkbox` tag,

it was much easier to add and remove code from the page without having
to recompile the entire application again and have to wait for the build to
complete.

The most interesting part of the project was the way it was used.
It was used to build a large number of different web sites for
different customers. One day it might be a simple one-page
calculator, the next day it might be a complex multi-page
CRM system. The key was that the code was completely
separated from the presentation layer, so it was easy to
switch between different presentation layers without
having to change the underlying logic.

RESULTS

The observations resulting from this investigation are contained in the subsequent data sheets. The smooth data is plotted in Figures 1 to 8. Fig. 1 shows the results obtained on the $2\frac{1}{2}$ " engine with systematically varied cooling water flow rates. All other mechanical msp curves are for constant cooling water rate, and constant inlet oil and water temperatures. For purposes of easy comparison these data were plotted first for each engine in three different conditions of assembly, and again for each condition of assembly for the three different engines.

DISCUSSION

This investigation involved the first attempt to correlate the rate of cooling water flow between the three engines. After calibrating flow orifices, it was intended that each engine be run with equal flow per unit area. At the start of the work on the 2 $\frac{1}{2}$ " engine it became a matter of interest to determine any possible variation in friction as a function of coolant flow. Therefore runs were made at five different flow rates and the results plotted in Fig. 1. This curve shows no significant variation in mechanical mean effective pressure that can be attributed to flow rate alone. All other friction runs were then run at constant coolant flow rate per unit area.

Fig. 2 shows the results obtained on the 2 $\frac{1}{2}$ " engine. The results that were obtained in the "B" Condition both before and after dismantling the engine for new bearings are plotted in Fig. 9. No significant change in friction occurred after changing both main and bearing bearings from babbitt to bronze, increasing the conrod clearance and reducing the relative ring tension by more than one-half. The curves of Fig. 8 in the "A" Condition both with and without the oil seal show that this seal contributes a large proportion of the total friction particularly at low speeds where the seal probably operated largely in the boundary region of fluid friction. The complete engine or "A" Condition curve is significantly lower than that obtained by Gaboury et al., but it must be emphasized that in this investigation the engines were run without inlet and exhaust surge tanks or piping, so that the pumping contribution of Gaboury's curve cannot be compared on an identical basis.

Figure 3 is the result for the 4" engine. On this machine the "A" Condition curve is somewhat closer to Gaboury et al. than on the 2 $\frac{1}{2}$ " engine. Figure 4 is the plotted data for the 6" engine. The trends are comparable to the 4" machine.

Figure 5 is the result for the three engines in the "A" or complete engine condition. These curves show definitely that within the range of experimental error the motoring M.E.P is the same for all engines.

Figure 6 is the same for the "B" condition, and also shows that mechanical mean effective pressure for the three engines is the same within the limits of experimental accuracy.

Figure 7 is the "C" or bare-crankshaft condition of operation. These curves show a somewhat greater spread than conditions "B" and "A".

Figure 8 compares the friction developed in the 2" engine with and without the main oil seal. The friction contribution of this seal is large, particularly at low speed where the seal may operate largely in the boundary realm of fluid friction. It is manifestly difficult to design and obtain this type of seal on any basis that would guarantee geometric similitude. Among the variants would be rubber hardness, area of contact, the change of rubber properties with time and of course surface characteristics of the shaft. Note that the maximum friction contribution of the seal in the 2 $\frac{1}{2}$ " engine is approximately one-half the total for the "C" or bare-crank-shaft condition. It was also noted that in running without the oil seal the equilibrium temperatures of the main bearing were considerably lower than in the comparable condition with seals installed. A correction for oil viscosity might then magnify the difference between these two curves.

It was considered by the authors throughout the experimental work that the accuracy of reading the hydraulic scale was about .7 $\frac{1}{2}$ M.E.P (.2" mercury scale reading) varying slightly between engines.

A possible cause of disagreement with similar engine theory lies in the inherent difficulty of satisfying the requirement that M_E be the same in all engines (See Appendix "B"). Assuming that the viscosity-temperature characteristics of the three lubricating oils used would be similar, it is not likely

the addition of 7% salt at regular intervals did not affect soil pH which
 -and the effect was similar both at 0.05MCl and 0.005M concentrations.
 At 0.05MCl, there was no difference between the two treatments
 although their means were not significantly different and not at 7% salt.
 The 0.005MCl and 0.05MCl readings would not be statistically significant since the
standard error of the mean is approximately 0.001.
 The results indicate that the addition of 7% salt did not
 significantly reduce the soil microflora concentrations at 0.05MCl and 0.005MCl
 concentrations, yet the bacterial and fungal counts showed a slight increase
 over the control sample. This was also true for the 0.001MCl
 treatment and the 0.0005MCl treatment, but the 0.0001MCl
 treatment had a significant reduction in all three bacteria and fungi
 concentrations. The 0.00005MCl treatment had a significant
 reduction in all three bacteria and fungi concentrations. The 0.00001MCl
 treatment had a significant reduction in all three bacteria and fungi
 concentrations. The 0.000005MCl treatment had a significant
 reduction in all three bacteria and fungi concentrations. The 0.000001MCl
 treatment had a significant reduction in all three bacteria and fungi
 concentrations. The 0.0000005MCl treatment had a significant
 reduction in all three bacteria and fungi concentrations. The 0.0000001MCl
 treatment had a significant reduction in all three bacteria and fungi
 concentrations.

that the temperatures at the friction surfaces would be the same in all the engines. Still another cause for departure from theory is the fact that real bearings do not operate under the assumptions involved in the classical theory (Tetraoff) of lubrication, upon which the similar engine theory is based.

CONCLUSION

The conclusions arising from the data of this investigation are as follows:

1. The theory, which predicts that the F_{D1} and F_{D2} of similar engines operating at the same piston speed will be the same, is a valid one, for engines under motoring conditions.
2. The use of a contact type oil seal may introduce large friction forces and is a component of uncertain behaviour in experimental engines of this type.
3. The effect of cooling water velocity on F_{D1} is negligibly small for motoring conditions.

the development of the new system. The new system will be developed by the same team which developed the old system. The new system will be developed by the same team which developed the old system. The new system will be developed by the same team which developed the old system.

The new system will be developed by the same team which developed the old system. The new system will be developed by the same team which developed the old system. The new system will be developed by the same team which developed the old system.

The new system will be developed by the same team which developed the old system. The new system will be developed by the same team which developed the old system. The new system will be developed by the same team which developed the old system.

RECOMMENDATIONS

In view of the strong diversity between the motoring FMEP obtained by Jaschuric et al and the NO_x emission results of this investigation, it is recommended that more firing data be collected on the $2\frac{1}{2}''$ engine to (1) check previous data or (2) determine if the changes made on the engine during this investigation will have any effect upon FMEP firing.

The rubber contact type oil seals in all three engines should be replaced by a non-contact oil seal. If this is undertaken another series of motoring data should be collected to compare with the results of this thesis.

Another 1990 publication on zoonotic spirochete diseases will be made at the 25th International Congress on Diseases of Man in Paris, France, 1990, and the 14th International Conference on Malaria and other Tropical Diseases in Durban, South Africa, 1990. The 1990 International Congress on Diseases of Man will be held in Paris, France, 1990, and the 14th International Conference on Malaria and other Tropical Diseases will be held in Durban, South Africa, 1990.

APPENDIX "B"

FRICITION THEORY FOR GEOMETRICALLY
SIMILAR ENGINES (7)

1.) Viscous Friction

Using Petroff's Derivation for thick Film Lubrication:

$$F_{HP} = K \frac{D}{d} \mu N^2 D^3$$

In a Geometrically Similar System

$$\frac{D}{d} = \text{Constant}$$

$$\frac{N}{d} = \text{Constant}$$

$$\therefore F_{HP} \sim \mu N^2 D^3$$

$$F_{HP} \sim F_{MEP} V_d N \sim F_{MEP} N^2 D^3$$

$$\therefore F_{MEP} \sim \frac{\mu}{N} D^3$$

A \neq the same piston speed

$$F_{MEP} \sim \frac{\mu}{N}$$

2.) Coulomb Friction

$$F_{MEP} \sim f \frac{(\text{Load Pressure}) l^2 \cdot l}{V_d} \sim f (\text{Load Pressure})$$

The friction factor depends on surface finish and materials which should be the same in similar engines. Also in similar engines IMP (or Load Pressure) is the same at same piston speed. Therefore, for similar engines operating at the same piston speed the Coulomb FMEP should be the same.

EXERCISESEXERCISES FOR GROUP WORK(1) EXTENDED ANALYSIS(I) EXTENDED ANALYSIS

100. Monotonicity: Prove that $\sin x \geq x - \frac{x^3}{6}$ for all $x \in \mathbb{R}$.

$$\sin x \geq x - \frac{x^3}{6} \Leftrightarrow \sin x - x + \frac{x^3}{6} \geq 0$$

Let $f(x) = \sin x - x + \frac{x^3}{6}$. Then $f'(x) = \cos x - 1 + \frac{x^2}{2}$.

$$f'(x) = \cos x - 1 + \frac{x^2}{2}$$

$$f''(x) = -\sin x + x$$

$$f'''(x) = -\cos x + 1 \geq 0$$

$$f''(x) = -\sin x + x$$

Since $f''(0) = 0$, we have $f'''(0) > 0$.

$$\frac{d}{dx} f''(0) > 0$$

(II) APPLIED PROBLEMS(1) Extremum Problems: Find the extrema of

the function $y = \frac{1}{2}x^2 + \frac{1}{3}x^3 + \frac{1}{4}x^4$ on the interval $[0, 2]$.

First we find the derivative of the function: $y' = x + x^2 + x^3$. Then we find the roots of the equation $x + x^2 + x^3 = 0$, which are $x = 0$ and $x = -1$. Since $x = -1$ is outside the interval $[0, 2]$, we can ignore it. Now we find the values of the function at the endpoints and at the root $x = 0$:

$$y(0) = 0, \quad y(2) = 8 + \frac{16}{3} + 16 = \frac{80}{3}, \quad y(-1) = -1 - 1 - 1 = -3.$$

APPENDIX CLUBRICATIONS

In order to meet the similitude requirement that μ/l be the same for G.S. Engines, the viscosity of the oil used in each engine was adjusted by blending SAE 20 and SAE 60 lubricants in the proper quantities. The oils used had the properties listed in the following table.⁽¹⁾

Viscosity S.S.U.

<u>Engine</u>	<u>100°F.</u>	<u>130°F.</u>	<u>210°F.</u>	<u>Gravity</u>
2½"	549	160.3	52.8	.88
4"	828	339.0	76.2	.89
6"	1465	627.0	114.1	.90

Composition:

2½"	URSA P 20 (Texaco symbol)
4"	54% URSA P 60, 46% P 20 (By volume)
6"	95% URSA P 60, 5% P 20 " "

These oils are a straight mineral oil, wholly paraffin base, distilled, with no additives. The above samples give the same value of μ/l at 250°F. This temperature was adopted in Ref. 1 as an attempt to satisfy similitude requirements in all parts of the engine.

9.000000

9.000000

was not at 1400 but there were still some and few of them
which might have been due to successive and continuous
reinforcement and all observations on this and on the growth of both
(1) older plants and all individuals which had been also on

all day average

age group	9.000	9.001	9.002	9.003	9.004

 (yesterday) 00.0 1000, 00.0 1000, 00.0
 00.0 1000, 00.0 1000, 00.0

Individuals, and all other types, the lower average is the older ones
 These are the same ones and values which are available on all the
 older individuals which are now 1,000 and larger and which are found
 among which are the 1000 and smaller

APPENDIX "D"WATER FLOW MEASUREMENTS

The water flows were measured by means of ASME square edged orifices inserted in the line between the engine outlet and the water expansion tanks. The flow was controlled by a throttle valve inserted on the discharge side of the water pumps.

Each orifice was calibrated and the results plotted in Figs. D-1, D-2, and D-3.

The flow rates actually used were:

2"

4"

6"

0.15³/sec.

0.334³/sec.

0.864³/sec.

These flows were based on 0.024³/sec./in.² for all engines.

INTERVIEW WITH RAY

right "choose" him to travel up "Junction" with many others but
one "right" he's either "left" with himself until "out" of "University" sometimes
before without a lot of incidents like that or "just sitting down
in a chair" and "not doing nothing" so this "choose" has no meaning
with all certain where one has intentions one nothing about
